Helmholtz Institut Mainz

Ecole Joliot-Curie "Nucleus through the looking glass – High intensity stable and ISOL beam frontier"

La Villa Clythia – Fréjus – France – September 30-October 05, 2012

# What's on the menu this week?

## Lesson 1:

- Discovery of the transuranium elements:  $Z=93 - 112$
- Stability of superheavy elements I

## Lesson 2:

- Discovery of the transuranium elements:  $Z=113- \dots$
- Stability of superheavy elements II

## Lesson 3:

- Reactions: synthesis of SHE
- Search for new elements at GSI

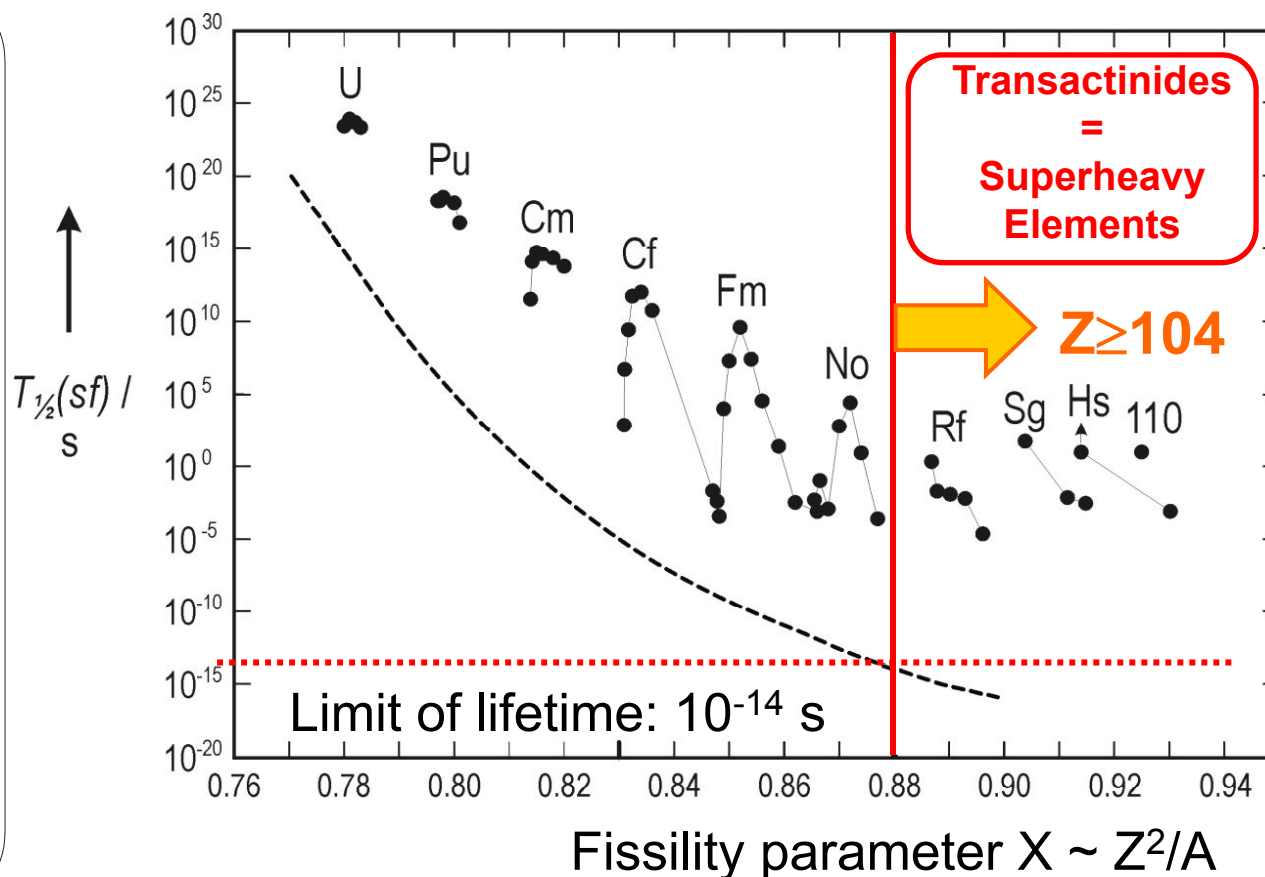

# What is a superheavy element

## Assumptions:

- 1.) "... composite nuclear systems that live less than about  $10^{-14}$  seconds (the generally accepted upper limit for a compound nucleus lifetime) shall not be considered a new element."

B.G. Harvey et al. Science 193 (1976) 1271

- 2.) "Superheavy Elements" is a synonym for "elements which only exist because of their (microscopical) shell stability."

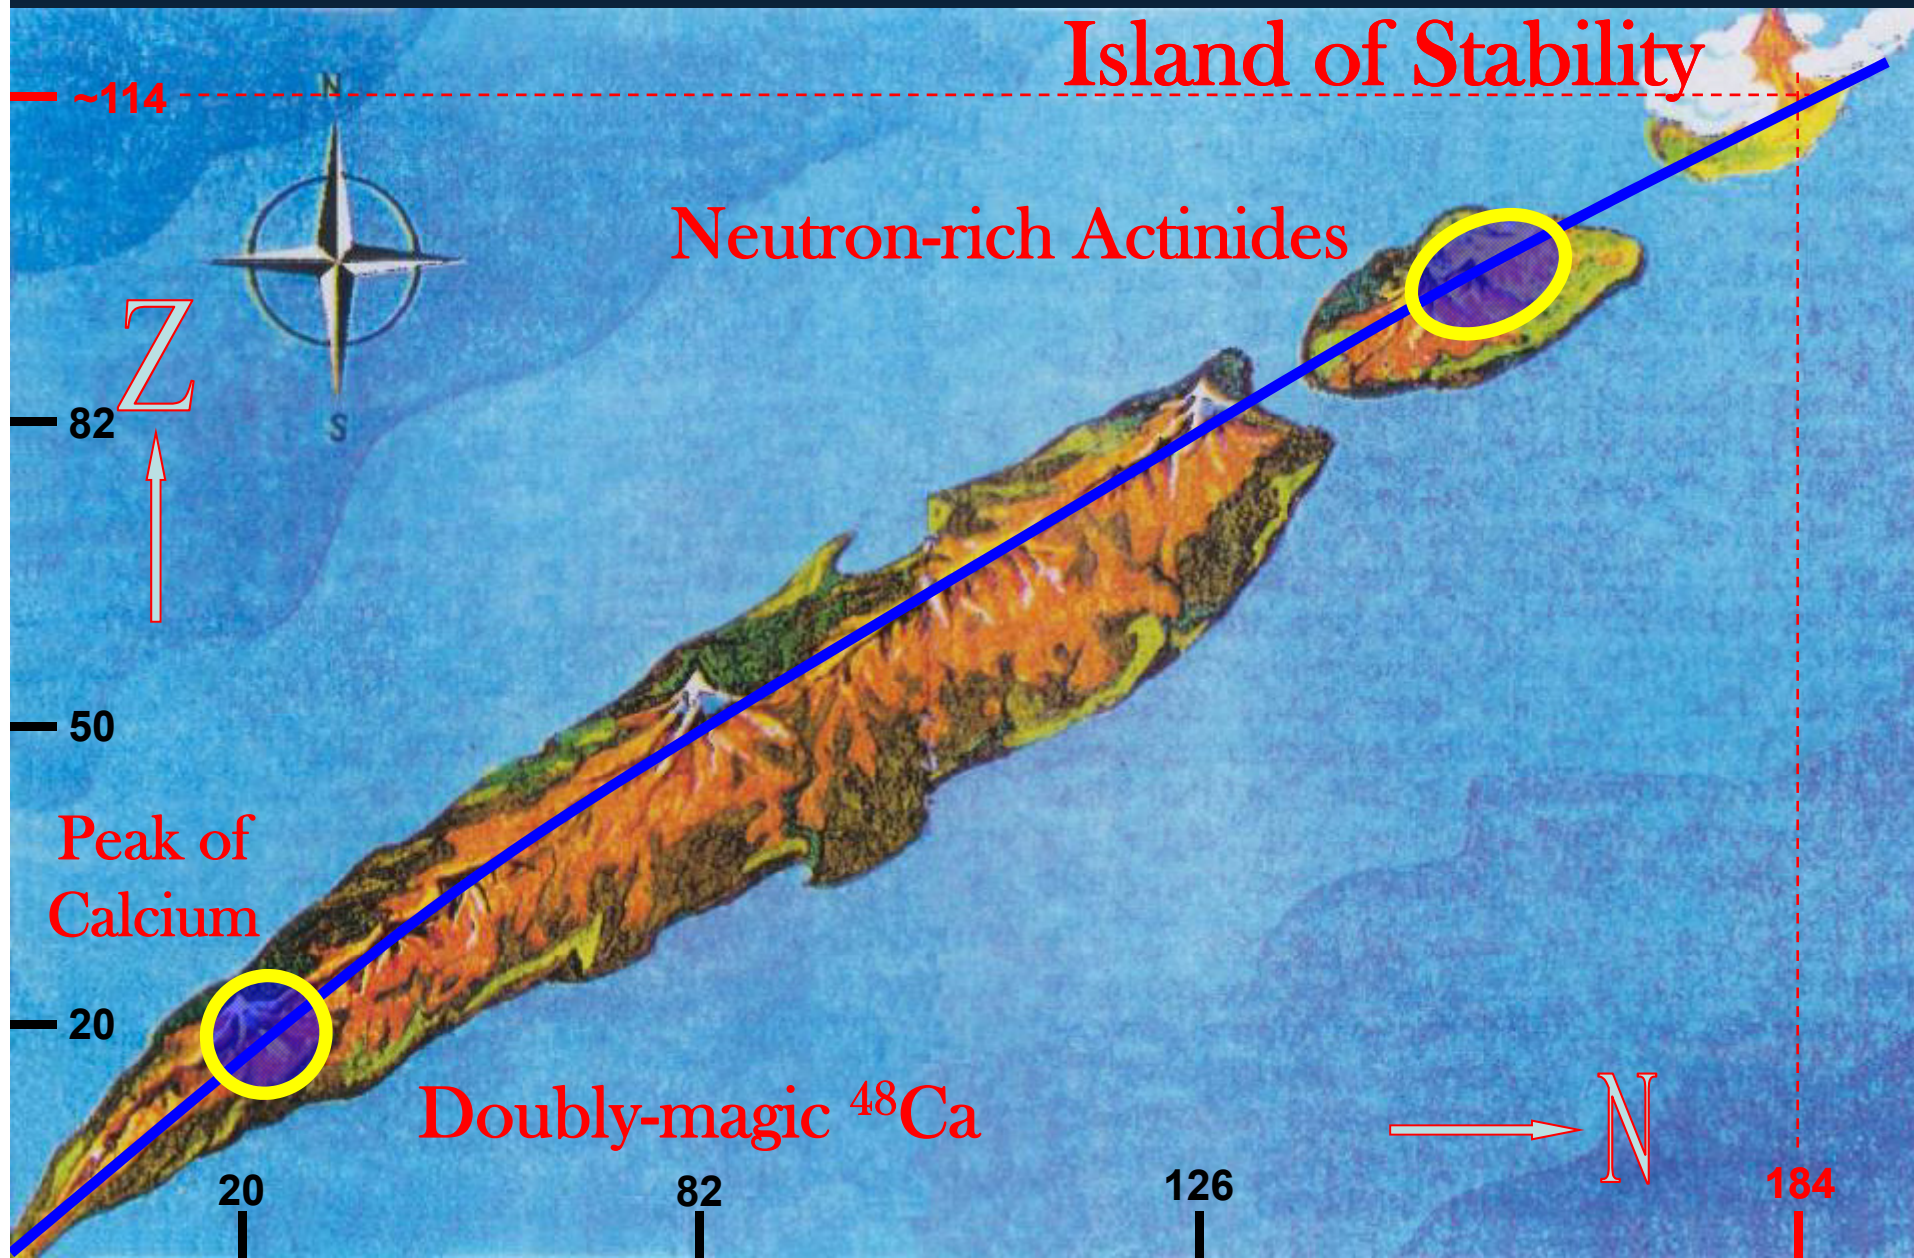

M. Schädel, 2007

## Japanese Physicists Claim Clinching Observation of New Superheavy Element

by Daniel Clery on 26 September 2012, 4:26 PM | [1 Comment](#)

[Email](#) [Print](#) | [f](#) [t](#) [g+](#) [1](#)

[More](#)

[PREVIOUS ARTICLE](#)

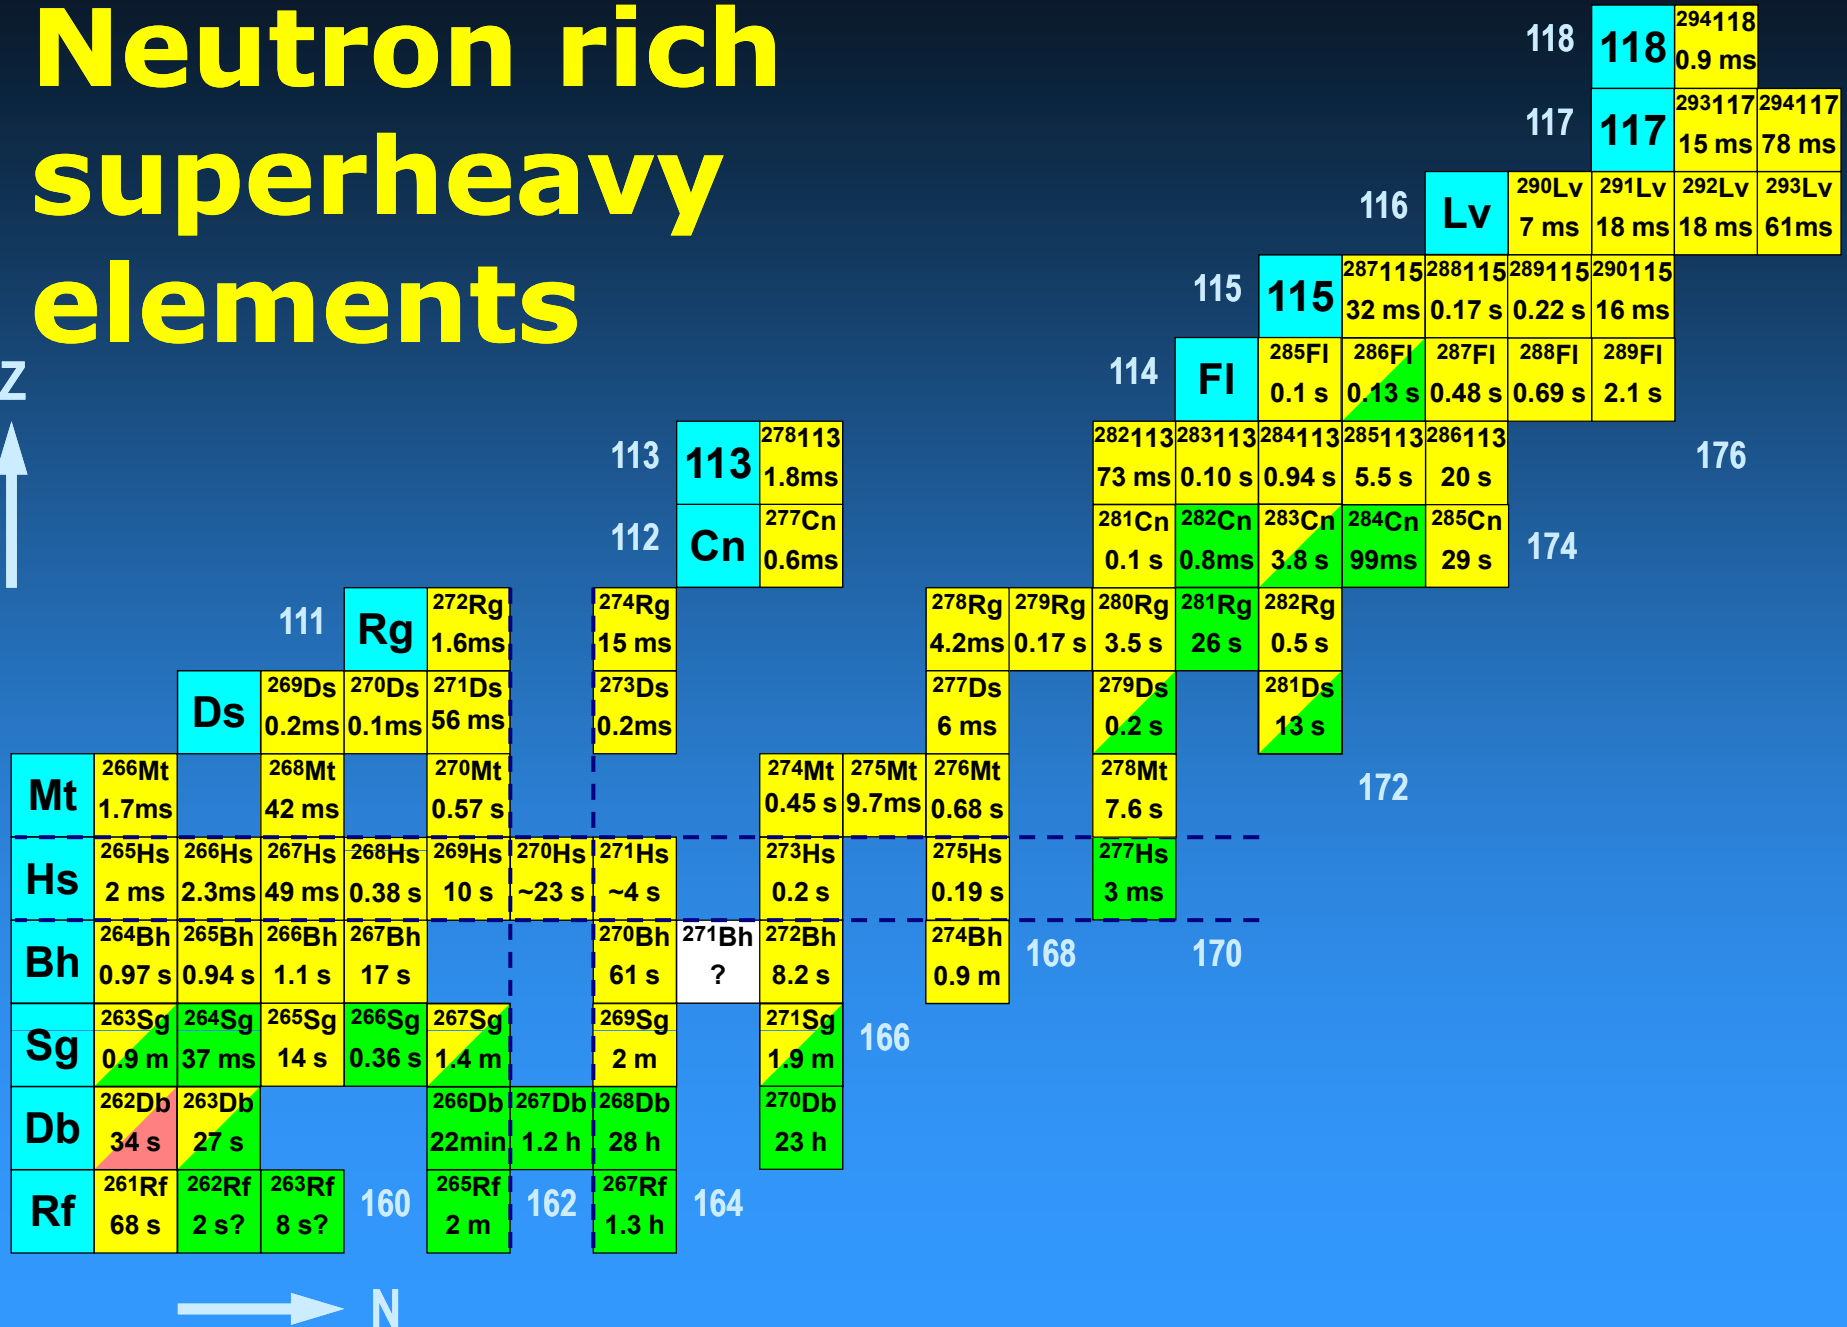

[NEXT ARTICLE](#)

The claim sounds simple enough: Physicists in Japan say they have made a new superheavy atom, element 113, which lies at the border of the periodic table. However, the backstory is far more complicated. And it illustrates just how arcane the business of spotting new superheavy elements can be.

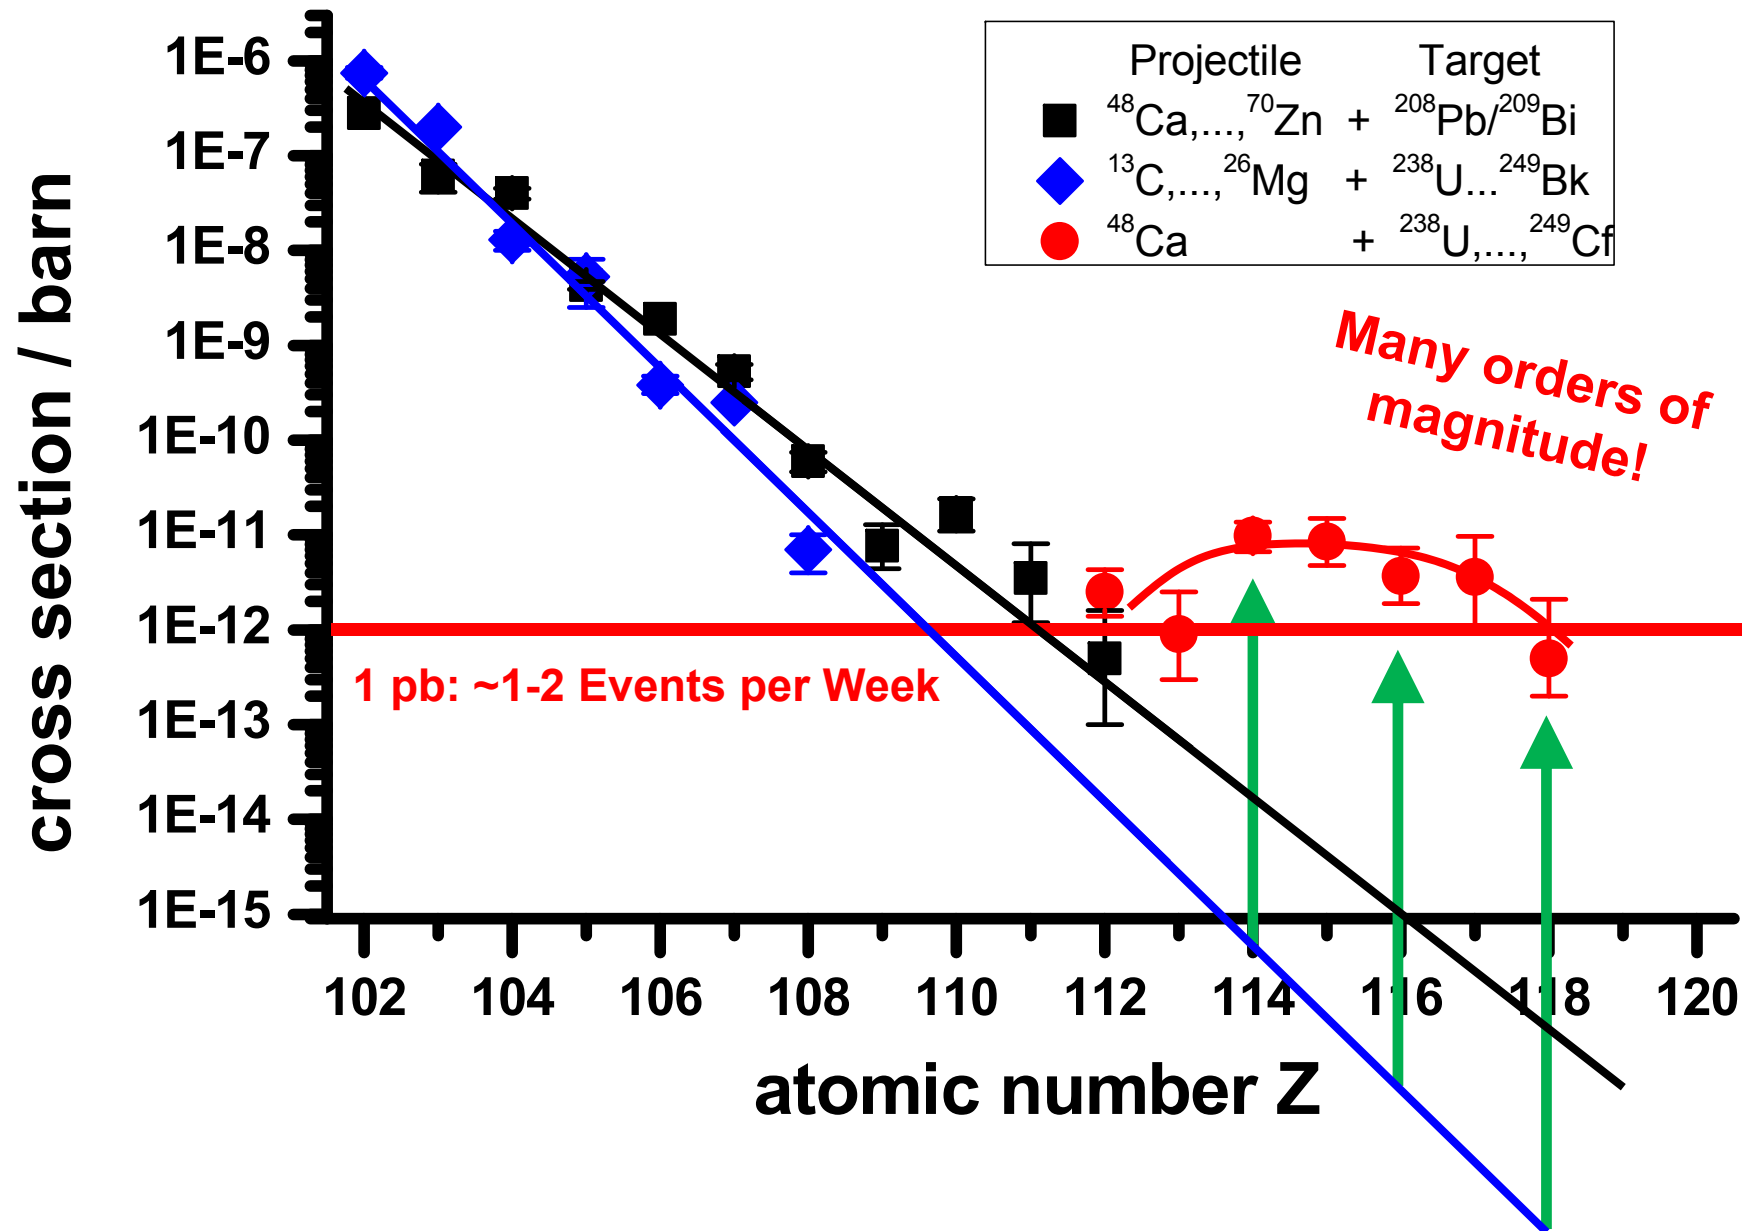

Z=117:  $^{249}\text{Bk}(^{48}\text{Ca},4n)^{293}\text{117}$

# Lessons learned

- All heaviest chemical elements have been discovered in physics experiments with recoil separators
- Reports on all elements up to  $Z=118$  published
- Cross sections drop exponentially in "cold (1n)" and "hot (5n)" fusion experiments, but are almost constant from  $Z=112-118$  in  $^{48}\text{Ca}$  induced reactions

# The element 113/115 decay chains from Dubna

# 2011 IUPAC/IUPAP assessment of Dubna claim for element 113

## *113; 03 The collaboration of Oganessian et al. [13]*

In 2007, this collaboration investigated the hot fusion of  $^{48}\text{Ca}$  with  $^{237}\text{Np}$  and reported two four-member  $\alpha$ -decay chains commencing at  $^{282}113$ , passing through  $^{278}\text{Rg}$ ,  $^{274}\text{Mt}$ , and  $^{270}\text{Bh}$ , and leading, in just one chain, to  $^{266}\text{Db}$  decay by spontaneous fission with a 32 min lifetime. The first two events in each chain showed excellent mutual agreement for both decay energies and lifetimes. The third member gave lifetimes of 470 and 810 ms. None of the nuclides had been previously characterized.

**JWP ASSESSMENT:** The collaborations of Oganessian et al. at Dubna were essentially contemporaneous with those of Morita et al. at RIKEN. The results are encouraging but do not meet the criteria for discovery because of the paucity of events, the lack of connections to known nuclides, and the absence of cross-bombardments.

# The element 113 decay chains from RIKEN

# 2011 IUPAC/IUPAP assessment of RIKEN claim for element 113

*113; 02 The collaboration of Morita et al. [10,11]*

Production of two chains of  $\alpha$ -emitting nuclides was reported by Morita et al. from the cold fusion reaction of a bismuth target with a  $^{70}\text{Zn}$  beam at the RIKEN heavy-ion facility in Japan, the first in 2004 [10] and the second in 2007 [11]. The former study reports the  $\alpha$ -chain commencing with  $^{278}113$  proceeding through  $^{274}\text{Rg}$ ,  $^{270}\text{Mt}$ ,  $^{266}\text{Bh}$ , and terminating via spontaneous fission decay assigned to  $^{262}\text{Db}$ . All  $\alpha$ -energies and lifetimes were measured. In the subsequent study, a very similar sequence was found but with some reproducibility difficulties. The full  $\alpha$ -energy for  $^{270}\text{Mt}$  was not measured; those for  $^{266}\text{Bh}$  were in disagreement (9.08 vs. 9.77 MeV); and the lifetimes for  $^{262}\text{Db}$  spontaneous fission were significantly different (41 vs. 0.8 s). For both chains, position-sensitive detectors were used. These provide a high degree of confidence that the observed decays are indeed sequential decays in each case. Nuclides reported in these chains do not correspond to established systems. But a single report of a triple-coincidence of  $\alpha$ -emitters commencing with  $^{266}\text{Bh}$  has been described by Wilk et al. [12]. Production was via the hot fusion  $^{22}\text{Ne} + ^{249}\text{Bk}$  reaction, and the leading event had an  $\alpha$ -particle energy of 9.29 MeV, within the uncertainties of the RIKEN results, with a lifetime of 1–10 s. It was followed by a 28 s  $\alpha$  decay, not by spontaneous fission. The latter observation is in contrast to the RIKEN result.

**JWP ASSESSMENT:** The work of the collaboration of Morita et al. is very promising but has not met the criteria for discovery owing to the paucity of events, the absence of firm connection(s) to known nuclides, and the inconsistencies noted above.

# TAsca Small Image mode SPECTroscopy

2

- Detailed spectroscopy towards  $Z=108/N=162$  ( $^{270}\text{Hs}$ )  
→ Input for SHE Island of Stability: **114 vs. 120 vs. 126**
- Fingerprinting SHE: Z identification via characteristic X-rays

E. E. Andersson et al., Nucl. Instrum. Meth. A 622 (2010) 101

# Lessons learned

- Elements up to 112, and 114/116 named.
- All elements up to 118 claimed.  
113/115/117/118 not approved
- No atomic number directly measured for any element beyond 112 (113...)
- New (last week) data on E113 from RIKEN

# Stability of SHE

**The atomic mass / binding energy**

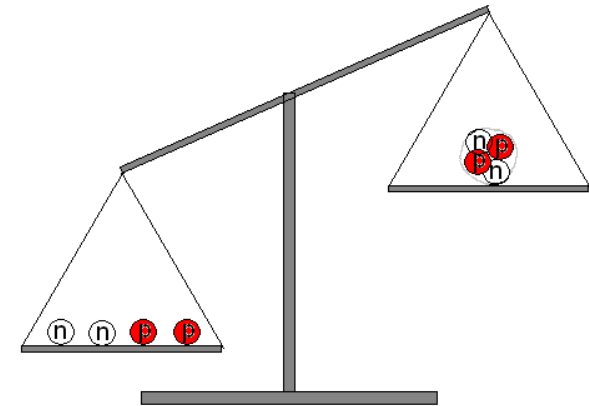

**Alpha decay**

# Mass ↔ Energy

A nucleus with Z protons and N neutrons is lighter than Z protons + N neutrons

→ Mass is converted to (binding) energy

The mass of a nucleus (or, an atom) gives direct information on its stability!

Relation between mass and energy:

$$E \text{ [J]} = m \text{ [kg]} \cdot (c \text{ [m/s]})^2$$

Atomic masses are given in the unit "u" (unified atomic mass)

**Definition:  $M(^{12}\text{C}) \equiv 12 \text{ u}$**

Using  $c=299'792'458 \text{ m/s}$  gives:  $1 \text{ MeV}/c^2 \hat{=} 1.073533 \cdot 10^{-3} \text{ u}$   
and  $1 \text{ u} \hat{=} 931.494 \text{ MeV}/c^2$ .

(Calculations "in energy": [MeV] or [J]; Calculations "in mass": [MeV/c<sup>2</sup>] or [kg])

# Atomic masses

$$M(Z,A) = Z \cdot M_H + (A-Z) \cdot M_N - BE/c^2$$

$M(Z,A)$ : Mass of the atom (MeV/c<sup>2</sup>)

Z: Protonen number

A: Mass number

$M_H$ : Mass of neutral H atom (938.791 MeV/c<sup>2</sup>=1.007823 u)

$M_N$ : Masse of neutron (939.573 MeV/c<sup>2</sup>=1.008662 u)

BE: Binding energy (MeV)

# The semi-empirical mass formula (SEMF)

BE consists of five contributions:

$$E_v = a_v \cdot A \quad a_v = 15.85 \text{ MeV}/c^2$$

$$E_s = a_s \cdot A^{2/3} \quad a_o = -18.34 \text{ MeV}/c^2$$

$$E_c = a_c \cdot Z^2/A^{1/3} \quad a_c = -0.71 \text{ MeV}/c^2$$

$$E_a = a_a \cdot (Z-A/2)^2/A \quad a_a = -92.86 \text{ MeV}/c^2$$

$$E_p = \begin{cases} +\delta & \text{for e,e-nuclei} \\ 0 & \text{for odd-A nuclei} \\ -\delta & \text{for o,o-nuclei} \end{cases}$$

$$\delta = a_p \cdot A^{-1/2} \quad a_p = 11.46 \text{ MeV}/c^2$$

Average deviation from  
experimental masses: <1%!

# The semi-empirical mass formula (SEMF)

BE consists of five contributions:

$$E_v = a_v \cdot A \quad a_v = 15.85 \text{ MeV}/c^2$$

$$E_s = a_s \cdot A^{2/3} \quad a_s = -18.34 \text{ MeV}/c^2$$

$$E_c = a_c \cdot Z^2/A^{1/3} \quad a_c = -0.71 \text{ MeV}/c^2$$

$$E_a = a_a \cdot (Z-A/2)^2/A \quad a_a = -92.86 \text{ MeV}/c^2$$

$$E_p = \begin{cases} +\delta & \text{for e,e-nuclei} \\ 0 & \text{for odd-A nuclei} \\ -\delta & \text{for o,o-nuclei} \end{cases}$$

$$\delta = a_p \cdot A^{-1/2} \quad a_p = 11.46 \text{ MeV}/c^2$$

Average deviation from  
experimental masses: <1%!

Example: BE of  $^{12}\text{C}$

$$E_v: \quad 190.20 \text{ MeV}/c^2$$

$$E_s: \quad -96.13 \text{ MeV}/c^2$$

$$E_c: \quad -11.16 \text{ MeV}/c^2$$

$$E_a: \quad 0.00 \text{ MeV}/c^2$$

$$E_p: \quad 3.31 \text{ MeV}/c^2$$

$$\text{BE:} \quad 86.22 \text{ MeV}/c^2$$

$$M(^{12}\text{C}): \quad 12.00636 \text{ u}$$

→ why not 12.0000 u ?

Example: BE of  $^{261}\text{Rf}$

$$E_v: \quad 4136.85 \text{ MeV}/c^2$$

$$E_s: \quad -749.02 \text{ MeV}/c^2$$

$$E_c: \quad -1201.65 \text{ MeV}/c^2$$

$$E_a: \quad -249.85 \text{ MeV}/c^2$$

$$E_p: \quad 0.00 \text{ MeV}/c^2$$

$$\text{BE:} \quad 1936.33 \text{ MeV}/c^2$$

$$M(^{261}\text{Rf}): \quad 261.095 \text{ u}$$

for comparison: AME2003: 261.109 u

# The $\alpha$ decay

Example:  $^{248}\text{Cm} \rightarrow ^{244}\text{Pu} + ^4\text{He}$

$$\Delta(^{248}\text{Cm}) = \Delta(^{244}\text{Pu}) + \Delta(^4\text{He}) + Q \quad (\Delta(Z,A) [\text{MeV}/c^2] = M(Z,A)[u] - A[u]$$

is the mass excess)

Decay energy:  $Q_\alpha [\text{MeV}] = \{\Delta(^{248}\text{Cm}) - [\Delta(^{244}\text{Pu}) + \Delta(^4\text{He})]\}c^2$

$Q_\alpha$  is distributed between the  $\alpha$  particle and the daughter. From momentum conservation follows the energie of the  $\alpha$  particle:

$$E_\alpha(^{248}\text{Cm}) = Q_\alpha \cdot \frac{M(^{244}\text{Pu})}{M(^{248}\text{Cm})}$$

and the recoil energy of the daughter

$$E_D(^{248}\text{Cm}) = Q_\alpha \cdot \frac{M(^4\text{He})}{M(^{248}\text{Cm})}$$

# Cs-Isotopes: mass in different mass models

K. Blaum, Phys. Rep. 425 (2006) 1

# Prediction of $E_{\alpha}$

Example:  $^{248}\text{Cm} \rightarrow ^{244}\text{Pu} + ^4\text{He}$

$$Q = \{\Delta(^{248}\text{Cm}) - [\Delta(^{244}\text{Pu}) + \Delta(^4\text{He})]\}c^2$$

	SEMF	AME 2003
$\Delta(^{248}\text{Cm})$ :	53.485 MeV/c <sup>2</sup>	67.392±0.005 MeV/c <sup>2</sup>
$\Delta(^{244}\text{Pu})$ :	45.658 MeV/c <sup>2</sup>	59.806±0.005 MeV/c <sup>2</sup>
$\Delta(^4\text{He})$ :	--	2.42491565±0.00000006 MeV/c <sup>2</sup>
$Q_{\alpha}(^{248}\text{Cm})$	5.402 MeV	5.16173 ±0.00025 MeV
$E_{\alpha}(^{248}\text{Cm})$	5.315 MeV	5.08 MeV

$^{248}\text{Cm}$   $\alpha$ -decay energy of the simple SEMF is precise to about 5%

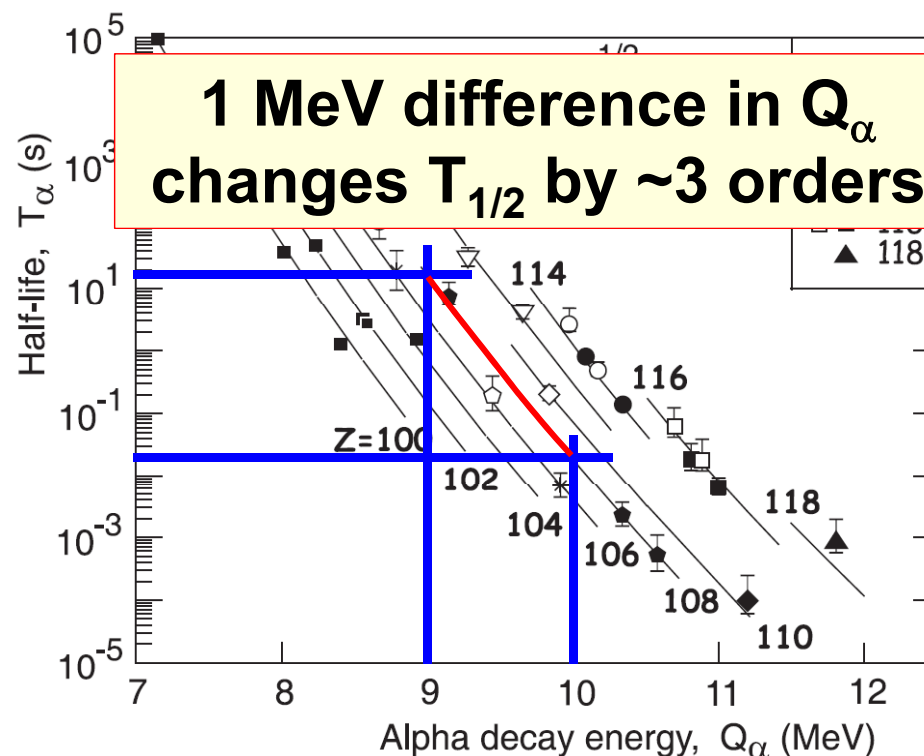

# Nuclear Physics 101: $\alpha$ -Decay

$$Q_{\alpha} [\text{MeV}] = \{ \Delta(\text{Mother}) - [\Delta(\text{Daughter}) + \Delta(^4\text{He})] \} c^2$$

# Geiger-Nuttall's rule in the region of the heaviest elements

Oganesson, Radiochim. Acta 2012

**Realistic estimate of stability of superheavy elements  
– including the border of the Periodic Table – requires good  
knowledge of nuclear masses**

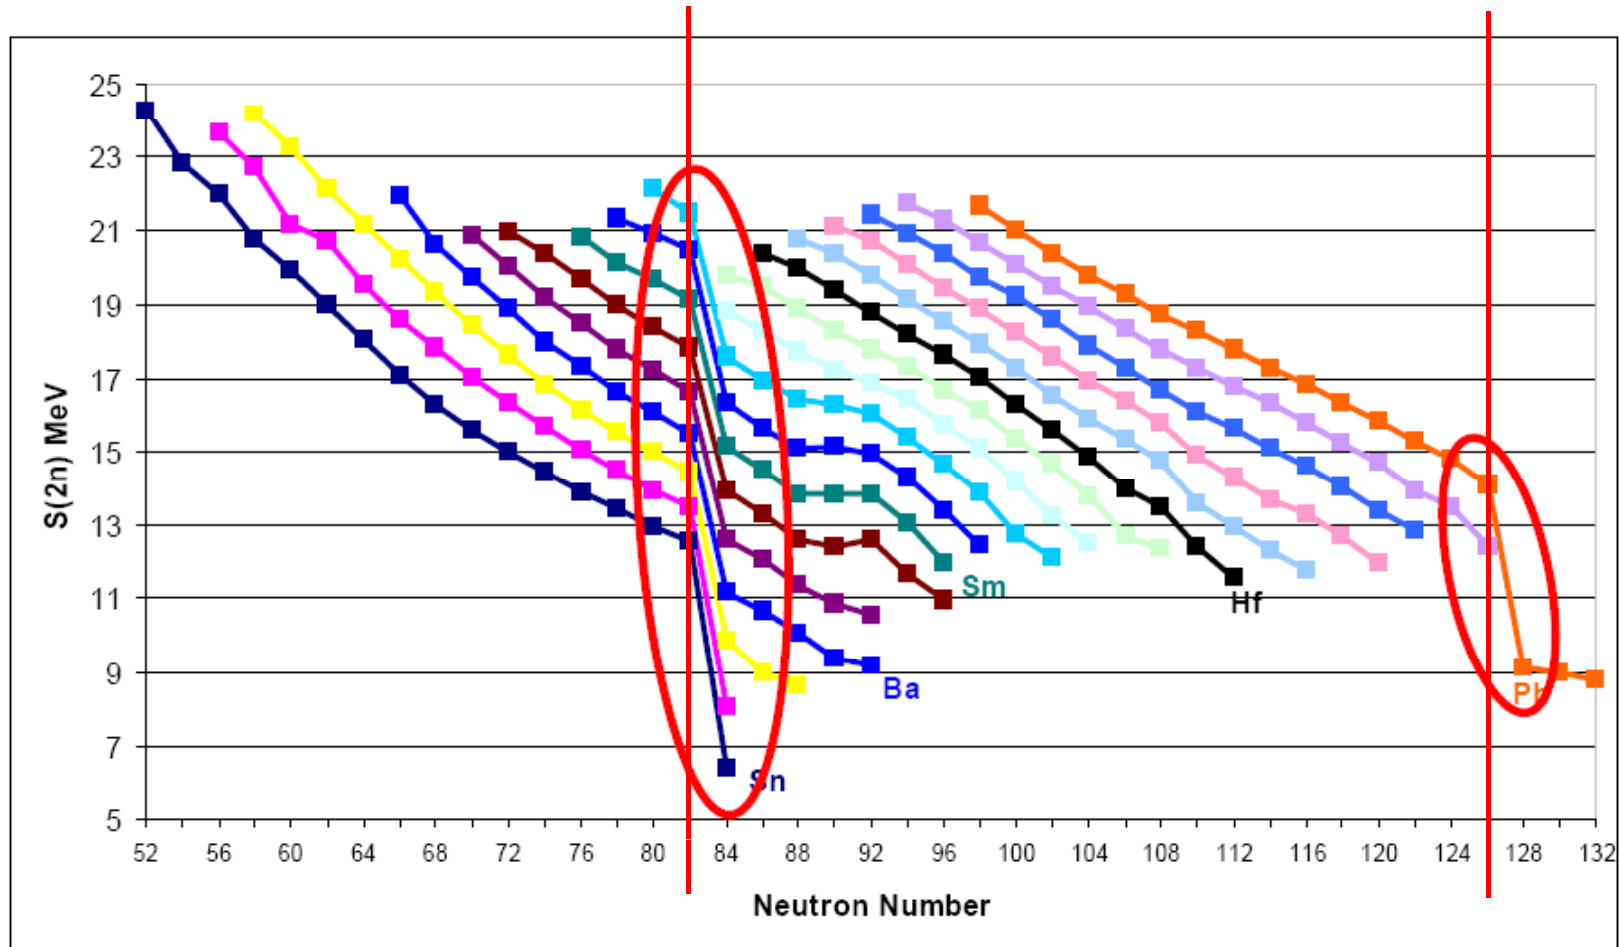

# Experimental weighing of the atom

$$E=mc^2$$

The perfect balance tells us about nuclear binding energy → stability of a nucleus

# Shell structure from masses

$$S_{2n}(Z, N) = m(Z, N-2) - m(Z, N) + 2m_n$$
